

HW #5

4.5:

Initialize variables, setting $\text{dist}[u]$ to 0, $\text{count}[u]$ to 1, $\text{dist}[v]$ to ∞ , and $\text{count}[v]$ to 0 for all $u \neq v$.

Then, can do BFS on G , starting with

Then, for each vertex x dequeued from Q :

for each neighbor y of x :

If $\text{dist}[y] = \infty$, then $\text{dist}[y] = \text{dist}[x] + 1$, and $\text{count}[y] = \text{count}[x]$. Then enqueue y .

But if $\text{dist}[y] = \text{dist}[x] + 1$, then $\text{count}[y] \neq \text{count}[x]$.

The time complexity is $O(|V| + |E|)$ when reformatting $\text{count}[v]$, which is linear.

4.14:

Can modify Dijkstra's for vertex cost

Initialize $\text{cost}[s] = C-s$, $\text{cost}[v] = \infty$ for all $v \neq s$, then priority queue H w/ $s, C-s$.

while H isn't empty, extract vertex u with min $\text{cost}[u]$. For each edge u, v in the edges of G :

new cost = $\text{cost}[u] + w_{u,v}$.

If new cost < $\text{cost}[v]$, then $\text{cost}[v] = \text{new cost}$, then update/insert v in H w/ priority $\text{cost}[v]$.

Finally, return $\text{cost}[t]$.

Time is $O((|V| + |E|) \log |V|)$.
